AMENDMENTS TO THE CLAIMS:

This listing of claims will replace all prior versions, and listings, of claims in the application:

Listing of Claims:

1. (Currently Amended)   A method comprising:

receiving data from a network application program interface (API) of a sending client, the data comprising a portion of an event to be sent from the sending client;

determining if the data is eligible for a security operation, wherein eligibility is determined by selector data contained in the data;

creating a selector based on the selector data, ~~wherein said selector indicates at least a portion of the data and a security association~~ and using said selector to search a database of security associations for at least one selector/security association pair identifying a security association corresponding to the selector, said database storing a plurality of selector/security association pairs corresponding to different timewise intervals of said event;

applying the security operation to the data if the data is eligible, wherein applying the security operation comprises using the security association on the at least a portion of the data; and

sending the data to which the security operation has been applied to a network protocol layer of the sending client.

2. (Currently Amended)   The method of claim 1, said event to be sent from the sending client to a receiving client, said database being local at said sending client, the

<u>receiving client storing a remote database comprising a similar plurality of selector/security</u>

<u>association pairs respectively corresponding to said different timewise intervals of said event</u>

~~further comprising:~~

~~using said selector to search a database of security associations for at least one~~

~~selector/security association pair identifying a security association corresponding to the~~

~~selector.~~

3. (Previously Presented)   The method of claim 2 wherein the selector data is

based at least in part on one of an internet protocol address taken from the data and a port

indicator taken from the data.

4. (Previously Presented)   The method of claim 1 wherein applying the security

operation comprises at least one of:

attaching a header to the data, said header including a security operation tag; and

encrypting the data.

5. (Currently Amended)   The method of claim [[1]] <u>2</u> ~~wherein determining if the~~

~~data is eligible for the security operation and applying the security operation if the data is~~

~~eligible depends, at least in part upon a local selector/security association pair at a sending~~

~~client corresponding to a remote selector/security association pair at a receiving client~~, said

local <u>database</u> selector/security association [[pair]] <u>pairs</u> and said remote <u>database</u>

selector/security association [[pair]] <u>pairs</u> having been received from a key server.

6. (Currently Amended)   A method comprising:

receiving data from a network protocol layer<u> of a receiving client, the data</u>

App. No. 09/544,493
Amendment Dated May 23, 2005
Reply to Office Action Dated November 23, 2004

PATENT
Customer No. 22,852
Attorney Docket No. 7451.0033-00
InterTrust Ref. No.: IT-47 (US)

comprising a portion of an event being received at the receiving client;

determining if the data is eligible for a security operation, wherein eligibility is determined by selector data contained in the data;

creating a selector based on the selector data, said selector indicating at least a portion of the data and a security association and using said selector to search a receiving client database of security associations for at least one selector/security association pair identifying a security association corresponding to the selector, said receiving client database storing a plurality of selector/security association pairs corresponding to different timewise intervals of said event;

applying the security operation to the data if the data is eligible wherein applying the security operation comprises using the security association on the at least a portion of the data; and

sending the data to which the security operation has been applied to a network application program interface (API) of the receiving client.

7. (Original)   The method of claim 6 wherein determining if the data is eligible for a security operation comprises at least one of:

detecting a security operation tag in a header of the data; and

detecting failure of an integrity check on the data.

8. (Currently Amended)   The method of claim 6, said event being sent from a sending client to the receiving client, the sending client storing a sending client database comprising a similar plurality of selector/security association pairs respectively corresponding to said different timewise intervals of said event further comprising:

using said selector to search a database of security associations for at least one

4

~~selector/security association pair identifying a security association corresponding to the~~

~~selector.~~

9. (Currently Amended)   The method of claim 8, <u>said receiving client database</u>

<u>selector/security association pairs and said sending client database selector/security</u>

<u>association pairs having been received from a key server</u> ~~further comprising:~~

~~blocking the data from being sent to the network API if no security association~~

~~corresponding to the selector is found~~.

10. (Currently Amended)   The method of claim 6 wherein determining if the data

is eligible for the security operation comprises [[:]] determining that the data is not eligible for

the security operation if [[a]] <u>the</u> selector ~~that references a database of security associations~~

cannot be created based on the <u>selector</u> data<u>, and wherein said data is sent to the network</u>

<u>API of the receiving client without an applied security operation if it is so determined that the</u>

<u>data is not eligible</u>.

11. (Canceled)

12. (Canceled)

13. (Previously Presented)   The method of claim 6 wherein the security association

comprises at least one of:

applying encryption to the data;

removing special packaging from the data;

applying decryption to the data; and

performing an integrity check on the data.

14. (Currently Amended)   A machine readable storage medium having stored

thereon machine executable instructions, execution of said machine executable instructions

being operable to implement a method comprising:

receiving data from a network application program interface (API)) of a

sending client, the data comprising a portion of an event to be sent from the sending client;

determining if the data is eligible for a security operation, wherein eligibility is

determined by selector data contained in the data;

creating a selector based on the selector data, ~~wherein said selector~~

~~indicates at least a portion of the data and a security association~~ and using said selector to

search a local sending client database of security associations for at least one

selector/security association pair identifying a security association corresponding to the

selector, said sending client database storing a plurality of selector/security association pairs

corresponding to a succession of timewise intervals of said event;

applying the security operation to the data if the data is eligible, wherein

applying the security operation comprises using the security association on the at least a

portion of the data; and

sending data to which the security operation has been applied to a network

protocol layer of the sending client.

15. (Currently Amended)   The machine readable storage medium of claim 14,

said event to be sent from the sending client to a receiving client having a remote database

comprising a similar plurality of selector/security association pairs respectively

corresponding to said succession of timewise intervals of said event ~~further comprising:~~

~~using said selector to search a database of security associations, for at least one~~

~~selector/security association pair identifying a corresponding a security association.~~

16. (Previously Presented)   The machine readable storage medium of claim 14

wherein the selector data is based at least in part on one of an internet protocol address

taken from the data and a port indicator taken from the data.

17. (Previously Presented)   The machine readable storage medium of claim 14

wherein applying the security operation comprises at least one of:

    attaching a header to the data, said header including a security operation tag;

    performing an integrity check; and

    encrypting the data.

18. (Currently Amended)   The machine readable storage medium of claim 14

~~wherein determining if the data is eligible for the security operation and applying the security~~

~~operation if the data is eligible depends upon a local selector/security association pair at a~~

~~sending client corresponding to a remote selector/security association pair at a receiving~~

~~client~~, said ~~local~~ sending client database selector/security association [[pair]] pairs and said

remote database selector/security association [[pair]] pairs having been received from a key

server.

19. (Currently Amended)   A machine readable storage medium having stored

thereon machine executable instructions, execution of said machine executable instructions

being operable to implement a method comprising:

    receiving data from a network protocol layer of a receiving client, the data

comprising a portion of an event being received at the receiving client;

determining if the data is eligible for a security operation, wherein eligibility is determined by selector data contained in the data;

creating a selector based on the selector data, said selector indicating at least a portion of the data and a security association and using said selector to search a local receiving client database of security associations for at least one selector/security association pair identifying a security association corresponding to the selector, said receiving client database storing a plurality of selector/security association pairs corresponding to a succession of timewise intervals of said event;

applying the security operation to the data if the data is eligible, wherein applying the security operation comprises using a security association on the at least a portion of the data; and

sending the data to which the security operation has been applied to a network application program interface (API) of the receiving client.

20. (Previously Presented)   The machine readable storage medium of claim 19 wherein determining if the data is eligible for a security operation comprises at least one of:

detecting a security operation tag in a header of the data; and

detecting failure of an integrity check on the data.

21. (Currently Amended)   The machine readable storage medium of claim 19, said event being sent from a sending client to the receiving client, the sending client storing a sending client database comprising a similar plurality of selector/security association pairs respectively corresponding to said succession of timewise intervals of said event further having stored thereon machine executable instruction, execution of said machine

~~executable instruction being operable to implement a method further comprising:~~

~~using said selector to search a database of security associations for at least one~~

~~selector/security association pair identifying a security association corresponding to the~~

~~selector.~~

22. (Currently Amended)   The machine readable storage medium of claim 21,

said receiving client database selector/security association pairs and said sending client

database selector/security association pairs having been received from a key server ~~further~~

~~comprising:~~

~~blocking the data from being sent to the network API if no security association~~

~~corresponding to the selector is found~~.

23. (Currently Amended)   The machine readable storage medium of claim 19

wherein determining if the data is eligible for the security operation comprises [[:]]

determining that the data is not eligible for the security operation if a selector ~~that references~~

~~a database of security associations~~ cannot be created based on the data, and wherein said

data is sent to the network API of the receiving client without an applied security operation if

it is so determined that the data is not eligible.

24. (Canceled)

25. (Canceled)

26. (Previously Presented)   The machine readable storage medium of claim 19

wherein the security association comprises at least one of :

28. (Currently Amended)   A management server apparatus <u>at a receiving client</u>

<u>receiving an event transmitted from a sending client, the event having a duration and being</u>

<u>divided into a succession of timewise intervals that are relatively short compared to said</u>

<u>event duration,</u> comprising:

a processing unit to:

<u>receive a plurality of selector/security association pairs from a key server</u>

<u>corresponding to said succession of timewise intervals of said event;</u>

receive data from a network protocol layer<u> of the receiving client, the data including a</u>

<u>portion of the event within one of said timewise intervals,</u>

determine if the data is eligible for a security operation, wherein eligibility is

determined by selector data contained in the data,

create a selector based on the selector data, said selector indicating at least a

portion of the data and a security association<u> associated with at least one of said</u>

<u>selector/security association pairs received from the key server;</u>

apply the security operation to the data if the data is eligible, wherein applying the

security operation comprises using the security association on the at least a portion of the

data, and

send the data to which the security operation has been applied to a network

application program interface (API) <u>of the receiving client.</u>

11
